Aviation Security and Passenger Safety **GS III**

- Aviation security protects aircraft, passengers and crew from deliberate threats such as hijacking or unlawful entry into the cockpit. **Restricted cockpit access** and reinforced doors reduce the possibility of attackers taking control of an aircraft during flight.

- Security measures can sometimes create new **operational difficulties**. A locked cockpit door may prevent an attacker from entering, but it can also delay assistance when a pilot faces an emergency. Safety planning must therefore consider both protection against threats and access during exceptional situations.

- Aircraft security depends on more than physical barriers. **Crew training**, emergency communication, passenger screening and procedures for identifying unusual behaviour help reduce risks. These measures must work together so that one security mechanism does not become the only defence against a serious threat.

- Aviation authorities must regularly review security rules as threats and technologies change. Investigations, **safety audits** and cooperation between airlines and regulators can reveal weaknesses. Effective procedures should protect passengers while preserving the crew's ability to respond quickly to emergencies.

Aviation security requires balancing protection against unlawful interference with emergency preparedness, ensuring that security barriers do not unintentionally compromise passenger safety.
